# Naïve Bayes algorithm 

Dr. Johan Hagelbäck

johan.hagelback@Inu.se
http://aiguy.org

## Algorithms for classification

- There are several algorithms that can be for classification tasks:
- Artificial Neural Networks
- Support Vector Machines
- k-Nearest Neighbor
- Decision Trees
- ... and many more
- We will focus on the basic but common algorithm Naïve Bayes
- It has several benefits such as high speed, and is often very effective for text classification

## Bayes' theorem

- First, we need to learn about Bayes' theorem
- It describes the probability of an event, based on prior knowledge of conditions that might be related to the event
- Bayes' theorem is stated using the following formula:

$$
P(A \mid B)=\frac{P(B \mid A) \cdot P(A)}{P(B)}
$$

- ... where $P(A \mid B)$ shall be interpreted as "probability that A occurs given B"
- It is best explained using an example:

## Example

- We are interested in knowing if "a stiff neck is a good sign of being a good FIFA player?"
- To answer this using Bayes' theorem we need to know the prior probabilities:
- 50\% of the good FIFA players have a stiff neck:
$P($ stiff $\mid$ good $)=0.5$
- One in 50000 players is good at FIFA: $P($ good $)=1 / 50000$
- One in 20 players suffer from a stiff neck:
$P($ stiff $)=1 / 20$

## Example

- We can now use the prior probabilities:
- $P($ stiff $\mid$ good $)=0.5 \quad P($ good $)=1 / 50000 \quad P($ stiff $)=1 / 20$
- ... to calculate the probability of being a good FIFA player if you have a stiff neck:

$$
\begin{aligned}
P(\text { good } \mid \text { stiff }) & =\frac{P(\text { stiff } \mid \text { good }) \cdot P(\text { good })}{P(\text { stiff })} \\
P(\text { good } \mid \text { stiff }) & =\frac{0.5 \cdot 1 / 50000}{1 / 20}=0.0002
\end{aligned}
$$

Linnæus University

## Example

- Given the prior probabilities:
- $P($ stiff $\mid$ good $)=0.5 \quad P($ good $)=1 / 50000 \quad P($ stiff $)=1 / 20$
- ... we can use Bayes' theorem to say that the probability that a player is good at FIFA if he has a stiff neck is 0.0002 , or one in 5000 players
- So even if $50 \%$ of the good FIFA players have a stiff neck, it is not a good indicator of being good or bad at FIFA

## Naive Baves

- Bayes' theorem only takes one attribute into consideration (stiff neck) when calculating the probability of belonging to a specific category (good FIFA player)
- In most real-world applications we have more than one attribute:
- stiff neck
- good gamepad
- high resolution TV with a large screen
- We need a way of combining several inputs to get a probability of belonging to a specific category
- This is handled by the Naïve Bayes classifier

## Naïve Bayes

- The classifier is called naïve because it assumes that the attributes are independent of each other
- It means that the probability of one attribute belonging to a specific category is completely unrelated to the probability of other attributes belonging to that category
- There are no relations between attributes!
- This is actually a false assumption for most tasks
- Example: "money" is a better spam indicator if in combination with "casino" than with "programming"

## Linnæus University

## Naïve Bayes

- The independence between attributes means that the actual probability calculated by the Naïve Bayes classifier is inaccurate
- You cannot say that the resulting probability is the actual probability that an example belongs to a category
- We can however compare the results of the example belonging to different categories, and see which category has the highest probability
- This works surprisingly well for many real-world classification problems

## Multinomial Naïve Bayes

- We will first take a look at the Multinomial Naïve Bayes algorithm
- It works best when the inputs are categorical or text
- Let's start with an example:

## Example dataset

| Game pad? | Stiff neck? | Player skill |
| :--- | :--- | :--- |
| Great | Yes | Good |
| Average | Yes | Good |
| Junk | Yes | Good |
| Average | No | Good |
| Junk | No | Bad |
| Average | No | Bad |
| Great | Yes | Bad |
| Average | No | Bad |
| Average | No | Bad |

## Linnæus University

## Frequency table

- First step is to generate a frequency table:

| Game Pad? |  |  | Stiff neck? |  |  | Player skill? |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Good | Bad |  | Good | Bad | Good | Bad |
| Great | 1 | 1 | Yes | 3 | 1 | 4 | 5 |
| Average | 2 | 3 | No | 1 | 4 |  |  |
| Junk | 1 | 1 |  |  |  |  |  |

| Game pad? | Stiff neck? | Player skill |
| :--- | :--- | :--- |
| Great | Yes | Good |
| Average | Yes | Good |
| Junk | Yes | Good |
| Average | No | Good |
| Junk | No | Bad |
| Average | No | Bad |
| Great | Yes | Bad |
| Average | No | Bad |
| Average | No | Bad |

Linnæus University
Average

## Prior probabilities

- We continue filling the table with prior probabilities:

| Game Pad? |  |  | Stiff neck? |  | Player skill? |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Good | Bad |  | Good | Bad | Good | Bad |
| Great | 1 | 1 | Yes | 3 | 1 | 4 | 5 |
| Average | 2 | 3 | No | 1 | 4 |  |  |
| Junk | 1 | 1 |  |  |  |  |  |
| P(Great $\mid x)$ | $1 / 4$ | $1 / 5$ | $P($ Yes $\mid x)$ | $3 / 4$ | $1 / 5$ | $4 / 9$ | $5 / 9$ |
| $P($ Avg $\mid x)$ | $2 / 4$ | $3 / 5$ | $P($ No $\mid x)$ | $1 / 4$ | $4 / 5$ |  |  |
| $P($ Junk $\mid x)$ | $1 / 4$ | $1 / 5$ |  |  |  |  |  |

Linnæus University

## Classification

- The table is all we need for classification
- Now we can answer questions like:
- A player has an average game pad and a stiff neck. Is he a good or bad player?
- We have two possible categories, Good or Bad player
- Let's calculate the probabilities of the above mentioned player belonging to the two categories:

Linnæus University

## Classification

- Classify the player:
- \{game pad $=$ average, stiff neck $=$ yes $\}$
- Probability that the player is Good:

$$
P(\text { Good ) * P(average | Good) * P(yes | Good) }=4 / 9 \text { * 2/4 * } 3 / 4=0.1667
$$

- Probability that the player is Bad:

$$
P(\text { Bad }) * P(\text { average } \mid \text { Bad }) * P(\text { yes } \mid \text { Bad })=5 / 9 * 3 / 5 * 1 / 5=0.0667
$$

- Good has higher probability than Bad, so we classify the player as Good!

## Linnæus University

## Another example

- Classify the player:
- \{game pad = great, stiff neck = no\}
- Probability that the player is Good:

$$
P(\text { Good }) * P(\text { great } \mid \text { Good }) * P(\text { no } \mid \text { Good })=4 / 9 * 1 / 4 * 1 / 4=0.0278
$$

- Probability that the player is Bad:

$$
P(\text { Bad }) * P(\text { great | Bad }) * P(\text { no | Bad })=5 / 9 * 1 / 5 * 4 / 5=0.0889
$$

- Bad has higher probability than Good, so we classify the player as Bad!

## Threshold

- In many applications it is better to return a "don't know" than a misclassified example
- For example in spam filtering, it is often desirable to avoid having nonspam emails end up in the spam folder than to catch every single spam message
- This can be solved by using a threshold
- A threshold of 3 means that the probability for the highest category must be at least 3 times higher than the probability of the other category, otherwise the classifier is unsure
- In our examples we used a threshold of 1, meaning that we always classify an example as the highest category regardless of the difference in probabilities

## Linnæus University

## The examples using threshold

| \{game pad = average, stiff neck = yes\} |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| $P($ Good $)$ | $P($ Bad $)$ | Ratio | Threshold | Classified as |
| 0.1667 | 0.0667 | 2.499 | 1 | Good |
| 0.1667 | 0.0667 | 2.499 | 3 | Don't know |

| \{game pad great, stiff neck $=$ no\} |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| $P($ Good $)$ | $P($ Bad $)$ | Ratio | Threshold | Classified as |
| 0.0278 | 0.0889 | 3.198 | 1 | Bad |
| 0.0278 | 0.0889 | 3.198 | 3 | Bad |

Linnæus University

## Text classification

- In the examples we have seen so far we have had two nominal attributes:
- Game pad: \{great, average, junk\}
- Stiff neck: \{yes, no\}
- In text classification, we have to classify texts of different length
- To do this we first have to convert the text contents of each document to a bag-of-words (number of times each unique word is found in a text)
- Then we have to count the frequency and calculate the probability for each word belonging to each category
- Let's look at an example:

## Example dataset

| Text | Spam? |
| :--- | :--- |
| Buy cheap Rolex? | Yes |
| You want cheap Vicodin? | Yes |
| Can you buy milk? | No |
| Want candy tonight? | No |
| Gym tonight? | No |

- The unique words are (special characters removed):
- buy, cheap, rolex, you, want, vicodin, can, milk, candy, tonight, gym
- First step is to create a frequency matrix

## Linnæus University

## Frequency table

|  |  |  |  | Spam? |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Yes | No |  | Yes | No | Yes | No |
| buy | 1 | 1 | can | 0 | 1 | 2 | 3 |
| cheap | 2 | 0 | milk | 0 | 1 |  |  |
| rolex | 1 | 0 | candy | 0 | 1 |  |  |
| you | 1 | 1 | tonight | 0 | 2 |  |  |
| want | 1 | 1 | gym | 0 | 1 |  |  |
| vicodin | 1 | 0 |  |  |  |  |  |

Let's continue with the probabilities...

## Linnæus University

## Prior probabilities

|  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Yes | No |  | Yes | No | Yes | No |
| buy | 1 | 1 | can | 0 | 1 | 2 | 3 |
| cheap | 2 | 0 | milk | 0 | 1 |  |  |
| rolex | 1 | 0 | candy | 0 | 1 |  |  |
| you | 1 | 1 | tonight | 0 | 2 |  |  |
| want | 1 | 1 | gym | 0 | 1 |  |  |
| vicodin | 1 | 0 |  |  |  | $2 / 5$ | $3 / 5$ |
| $P($ buy $\mid x)$ | $1 / 2$ | $1 / 3$ | $P($ can $\mid x)$ | $0 / 2$ | $1 / 3$ |  |  |
| $P($ cheap $\mid x)$ | $2 / 2$ | $0 / 3$ | $P($ milk $\mid x)$ | $0 / 2$ | $1 / 3$ |  |  |
| $P($ rolex $\mid x)$ | $1 / 2$ | $0 / 3$ | $P($ candy $\mid x)$ | $0 / 2$ | $1 / 3$ |  |  |
| $P($ you $\mid x)$ | $1 / 2$ | $1 / 3$ | $P($ tonight $\mid x)$ | $0 / 2$ | $2 / 3$ |  |  |
| $P($ want $\mid x)$ | $1 / 2$ | $1 / 3$ | $P($ gym $\mid x)$ | $0 / 2$ | $1 / 3$ |  |  |
| $P($ vicodin $\mid x)$ | $1 / 2$ | $0 / 3$ |  |  |  |  |  |

Linnæus University

## Classification

- Now you want to classify the text "buy cheap candy"
- As in the previous examples, we calculate the probability for being spam or not being spam:

$$
P(\text { yes }) * P(\text { buy | yes) * } P(\text { cheap } \mid \text { yes }) * P(\text { candy } \mid \text { yes })=2 / 5 * 1 / 2 * 2 / 2 * 0 / 2=0
$$

- Here we can see a problem: if a word has never showed up in a category, we multiply with a 0 and the result will always be 0...
- To solve this we can apply Laplace correction:

## Laplace correction

- In Laplace correction we always add some constant value to each probability to avoid 0 probabilities
- If we use $1 / 3$ as Laplace correction the probability for being spam looks like:

```
P(yes) * P(buy | yes) * P(cheap | yes) * P(candy | yes) =
    = 2/5 * (1/2+1/3) * (2/2+1/3) * (0/2+1/3) =
    = 0.4 * 0.833 * 1.333 * 0.333 = 2.9
```

- And for not being spam:

$$
\begin{aligned}
& P(\text { no }) * P(\text { buy | no) * } P(\text { cheap | no }) * P(\text { candy | no })= \\
& =3 / 5 *(1 / 3+1 / 3) *(0 / 3+1 / 3) *(1 / 3+1 / 3)= \\
& =0.6 * 0.667 * 0.333 * 0.667=0.089
\end{aligned}
$$

- This message is classified as spam!

## Spam or not?

- The text "buy cheap candy" was clearly classified as spam
- Is this correct?
- The word that is most prominent in the result is "cheap", which exists in 2 of 2 spam and 0 of 3 non-spam messages
- If "cheap" is not a good indicator for spam, we need more training data where cheap appears in non-spam messages
- We need quite large amounts of data for text classification to be accurate

## Other variants of Naïve Bayes

- The approach described here is called Multinomial Naïve Bayes
- There are a number of other variants of Naïve Bayes, mainly Gaussian and Bernoulli
- In Bernoulli, we don't count the actual frequency of an attribute in a category
- Instead we use 1 if the attribute appears in any document belonging to the category, and 0 otherwise
- In Gaussian, we assume that attributes are numeric and follow a normal distribution
- It is used when inputs are numerical
- Let's take a look at how it works:

## Example: reduced Iris dataset

| Petal Length | Petal Width | Class |
| :--- | :--- | :--- |
| 1.4 | 0.2 | Iris-setosa |
| 1.3 | 0.2 | Iris-setosa |
| 1.5 | 0.2 | Iris-setosa |
| 1.4 | 0.2 | Iris-setosa |
| 1.7 | 0.4 | Iris-setosa |
| 1.4 | 0.3 | Iris-setosa |
| 3.7 | 1.0 | Iris-versicolor |
| 3.9 | 1.2 | Iris-versicolor |
| 5.1 | 1.6 | Iris-versicolor |
| 4.5 | 1.5 | Iris-versicolor |
| 4.5 | 1.6 | Iris-versicolor |
| 4.7 | 1.5 | Iris-versicolor |

## Linnæus University

## Training

- First, we divide the dataset into each category
- Then we calculate the mean value of each attribute for each category:

$$
\bar{x}=\frac{1}{n}\left(\sum_{i=1}^{n} x_{i}\right)=\frac{x_{1}+x_{2}+\cdots+x_{n}}{n}
$$

- And the standard deviation (how much each value differs from the mean) of each attribute for each category:

$$
s=\sqrt{\frac{1}{N-1} \sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}},
$$

Linnæus University

## Training

|  | Iris-S | tosa |  | Iris-ve | icolor |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Petal Length | Petal Width |  | Petal Length | Petal Width |
|  | 1.4 | 0.2 |  | 3.7 | 1.0 |
|  | 1.3 | 0.2 |  | 3.9 | 1.2 |
|  | 1.5 | 0.2 |  | 5.1 | 1.6 |
|  | 1.4 | 0.2 |  | 4.5 | 1.5 |
|  | 1.7 | 0.4 |  | 4.5 | 1.6 |
|  | 1.4 | 0.3 |  | 4.7 | 1.5 |
| Mean | 1.45 | 0.25 | Mean | 4.40 | 1.40 |
| Stdev | 0.14 | 0.08 | Stdev | 0.52 | 0.24 |

## Linnæus University

## Classification

- To classify new examples, we need to calculate the probabilities of the input attributes belonging to each category using the Gaussian Probability Density Function (PDF):

$$
\left.\left.\operatorname{pdf}\left(x_{i}, \operatorname{mean}_{\mathrm{i}}, \operatorname{std}_{\mathrm{i}}\right)=\left(1 /\left(\operatorname{sqrt}\left(2^{*} \mathrm{Pl}\right)\right)^{*} \operatorname{std}_{\mathrm{i}}\right)\right)^{*} \mathrm{e}^{\wedge}\left(-\left(\left(\mathrm{x}_{\mathrm{i}}-\text { mean }_{\mathrm{i}}\right)^{\wedge} 2\right) /\left(2^{*} \operatorname{std}_{\mathrm{i}}^{\wedge} 2\right)\right)\right)
$$

- Next, we multiply the probabilities for all attributes for each category
- Each probability is then normalized by dividing with the sum of the probabilities for all categories
- We classify the example as the category with the highest probability

## Linnæus University

## Classification

| IriS-SetOSa |  |  |
| :--- | :--- | :--- |
|  | Petal <br> Length | Petal Width |
| Mean | 1.45 | 0.25 |
| Stdev | 0.14 | 0.08 |
| $x$ | 1.6 | 0.8 |
| $P D F$ | 1.601 | $1.970 \mathrm{e}-09$ |
| $P$ | $3.154 \mathrm{e}-09$ |  |
| $P_{\text {norm }}$ | 0.102 |  |

| Iris-Versicolor |  |  |
| :--- | :--- | :--- |
|  | Petal <br> Length | Petal Width |
| Mean | 4.40 | 1.40 |
| Stdev | 0.52 | 0.24 |
| $x$ | 1.6 | 0.8 |
| PDF | $3.424 \mathrm{e}-07$ | 0.081 |
| $P$ | $2.776 \mathrm{e}-08$ |  |
| $P_{\text {norm }}$ | 0.898 |  |

The probability of the example belonging to Iris-versicolor is 0.898 , so we classify this flower as an Iris-versicolor

## Linnæus University

## Log probabilities

- The probability for each attribute belonging to a category is typically very small
- Multiplying lots of small values can lead to numerical underflow
- This is fixed by combining the log of the probabilities together
- This is done by:

1. Transform attributes $x$ and $y$ as $\ln (x)$ and $\ln (y)$

- natural logarithm, often called Math.log(x) or Math.log(x,Math.E)

2. Perform the log equivalent to multiplication, which is addition: $\ln (x y)=\ln (x)+\ln (y)$
3. Transform the equivalent product $\ln (x y)$ back into the original form: $e^{\ln (x y)}$

- often called Math.exp(value)

## Log probabilities

| IriS-SetOSa |  |  |
| :--- | :--- | :--- |
|  | Petal <br> Length | Petal Width |
| Mean | 1.45 | 0.25 |
| Stdev | 0.14 | 0.08 |
| $x$ | 1.6 | 0.8 |
| PDF | 1.601 | $1.970 \mathrm{e}-09$ |
| $\ln ($ PDF $)$ | 0.471 | -20.045 |
| $\sum \ln ($ PDF $)$ | -19.575 |  |
| $e^{\Sigma \ln (P D F)}$ | $3.154 \mathrm{e}-09$ |  |
| $P_{\text {norm }}$ | 0.102 |  |
|  |  |  |

| Iris-Versicolor |  |  |
| :--- | :--- | :--- |
|  | Petal <br> Length | Petal Width |
| Mean | 4.40 | 1.40 |
| Stdev | 0.52 | 0.24 |
| $x$ | 1.6 | 0.8 |
| PDF | $3.424 \mathrm{e}-07$ | 0.081 |
| $\ln$ (PDF) | -14.887 | -2.512 |
| $\sum \ln$ (PDF) | -17.400 |  |
| $e^{\Sigma \ln (P D F)}$ | $2.776 \mathrm{e}-08$ |  |
| $P_{\text {norm }}$ | 0.898 |  |

Same result, but we avoid possible numerical underflow

## Linnæus University

## Summary

- Despite its simplicity, Naïve Bayes is often effective for text classification and numerical datasets that are not too complex
- Since it is very fast, you can use it as a baseline to compare performance of other, more complex algorithms

## Test it on some datasets

Naïve Bayes

Accuracy: 99.75\% (393/394 correctly classified)

Random Forest

Accuracy: 100.00\% (394/394 correctly classified)

## Test it on some datasets

Naïve Bayes
Accuracy: $93.03 \%$ (347/373 correctly classified)

Random Forest

Accuracy: $100.00 \%$ (373/373 correctly classified)

Linnæus University
